

MyCCAngel — AI-Powered Healthcare Community Platform for IBD Patients

Founding Product Lead | 2024–Present (paused, restructuring) | Team of up to 8

Overview

MyCCAngel is a healthcare platform built to give people living with Inflammatory Bowel Disease (IBD) a trusted community, centralized resources, and AI-personalized support. As Founding Product Lead, I owned product strategy, UX direction, AI feature development, and day-to-day collaboration with designers and engineers — taking the product from concept to a substantial working build before development paused due to team attrition.

What I Built

- **Patient verification model (SVM, ~91% accuracy):** trained on a manually labeled dataset of 200 reports (held-out test split), gating platform signup to verified IBD patients only.
- **Recommendation engine:** personalizes each new user's experience using 20+ onboarding signals (diagnosis type, severity, daily-life impact).
- **AI chatbot UI/UX:** defined requirements and designed the full interface; development team built the NLP/ML pipeline (functional, IBD-specific training was the next step before pausing).
- **Product & UX direction:** initiated UX flows and screen designs, collaborated directly with designer in Figma; all core pages designed and most of frontend built.
- **Onboarding survey design:** 3-part patient intake questionnaire engineered specifically to feed both verification and recommendation models.
- **PostgreSQL schema:** designed the full relational data model including verification, consent, audit, and crowdsourced location tables.

Verification Pipeline

Medical report upload → OCR extraction → text cleaning → SVM classification → verification decision

Scope & Status

The two AI models and core community/profile functionality are fully built. A broader feature set — resource directories, toilet locator, events, and symptom-specific content hubs — was scoped and designed but not all reached implementation before the team paused. Backend development was underway on the signup/verification chain when the project paused. The chatbot pipeline was built by the team and functional; IBD-specific training was the next planned step.

Why It Mattered

The verification model protected the core trust mechanic of a patient-only community — a precision/recall tradeoff with direct product consequences, not just a modelling exercise. The recommendation engine and survey were built together as one system: every onboarding question existed because it fed a specific downstream output.
